Weight regain after bariatric surgery—how should it be defined?

Received April 26, 2016; accepted April 26, 2016

Definitions of weight regain collected in social media poll of IBC surgeons

Regaining weight to achieve a BMI > 35 [19]

An increase in weight of > 10 kg from nadir [11–15]

Any weight regain [16]

An increase in BMI of $\geq 5 \text{ kg/m}^2$ above the weight loss nadir [2]

Greater than 25% EWL regain with respect to minimal weight achieved after LSG [17,18]

IBC = International Bariatric Club; BMI = body mass index; EWL = excess weight loss; LSG = laparoscopic sleeve gastrectomy.

It is unacceptable that in the bariatric community more than 200 bariatric surgeons have proposed different bariatric procedures after failed sleeve gastrectomy and no consistent definition for weight regain exists. We emphasize the dire need for standardization of definitions for failure postbariatric surgery and an algorithm to clarify indications for subsequent revisional surgery procedures.

Conclusion

The results of this study have demonstrated that revisional surgery from OAGB to RYGB is an effective treatment in patients with post-OAGB refractory biliary reflux which was the most common indication for OAGB revision to RYGB leading to complete resolution of symptoms. However, it is associated with weight regain, albeit this may be acceptable to patients to treat biliary reflux as the weight gain is small over medium term. Alternative options for revisional surgery should be explored for patients who have failed to lose weight after OAGB as conversion to RYGB may lead to further weight gain. Hence, this data does not suggest that performing a RYGB for failure to lose weight or weight would be recommended.

Significant medium-term weight gain (J.61 BMI gain).
